## DATA SHARING

Most of these data are available from control-access repositories (dbGaP or the NIMH Human Genetics Initiative). By German law, GWAS data on German citizens cannot be deposited, and can only be accessed via collaboration with the study authors.

## DISCOVERY PHASE: MDD STUDIES & SAMPLES

**Table S2** summarizes the samples that comprise the discovery phase of the PGC MDD mega-analysis dataset. There are considerable similarities in the fundamental features of these studies. All subjects were of European ancestry. For cases, all subjects were assessed with a structured clinical interview and all met DSM-IV criteria for lifetime MDD (1). For three studies, case definitions required recurrent or recurrent/early-onset MDD. Cases were ascertained clinically in the majority of studies. Most of the control samples were population-based and all but one was screened to remove individuals with lifetime MDD.

**Table S2: Discovery sample characteristics**

Sample	Citation	Place	GWAS chip	Cases (DSM-IV)		Controls	
				Def	Source	Screened	Source
Bonn/Mannheim	(2)	GER	Illumina 610K	MDD	clin	no	pop

See below for sample acronyms. AUS=Australia. GER=Germany. NL=the Netherlands. US=United States. Mix=multiple sources of European subjects. MDD=major depressive disorder. rMDD=recurrent MDD. reOMDD=recurrent, early-onset MDD. Clin=clinical ascertainment. Pop=population-based ascertainment. Vol=volunteer sample.

The procedures used to establish each of these sample sets are described below.

#### Bonn/Mannheim (2)

Cases for the Bonn/Mannheim MDD study were ascertained from consecutive admissions to the inpatient units of the Department of Psychiatry and Psychotherapy at the University of Bonn and at the Central Institute of Mental Health in Mannheim, Germany. DSM-IV lifetime diagnoses of MDD were made by a consensus best-estimate procedure based on all available information, including a structured interview (SCID-I), medical records, and the family history method. In addition, the OPCRIT system was used to obtain detailed poly-diagnostic documentation of symptoms. Controls were ascertained from three population-based studies in Germany (Popgen, KORA, and Heinz-Nixdorf-Recall) and were asked for a lifetime history of MDD. Study protocols were reviewed and approved in advance by IRBs at participating institution. All subjects provided written informed consent.

Genetic Association Information Network (GAIN)-MDD (3)

The two parent projects that supplied subjects for this GWAS are large-scale longitudinal studies, the Netherlands Study of Depression and Anxiety (NESDA) and the Netherlands Twin Registry (NTR). Recruitment of participants for NESDA took place from 09/2004-02/2007, and ascertainment was from outpatient specialist mental health facilities, and primary care. Additional cases were from the population-based cohorts NEMESIS, ARIADNE and the NTR. Inclusion criteria were a lifetime diagnosis of DSM-IV MDD as diagnosed via the CIDI, age 18-65 years, and self-reported northwestern European ancestry. Persons who were not fluent in Dutch and those with a primary diagnosis of a psychotic disorder, obsessive compulsive disorder, bipolar disorder, or severe substance use dependence were excluded. Control subjects were mainly from the NTR. Longitudinal phenotyping includes assessment of depressive symptoms (via multiple instruments), anxiety, neuroticism, and personality measures. Inclusion for controls required no report of MDD at any measurement occasion, and low genetic liability for MDD. Controls were screened with specific queries about medication use or whether the subject had ever sought treatment for depression symptoms and/or via the CIDI interview. Low liability for MDD was determined by the use of a factor score derived from longitudinal measures of neuroticism, anxiety and depressive symptoms (mean 0, std 0.7); controls were required never to have scored highly ( $\geq 0.65$ ) on this factor score. A subset of controls were from NESDA and had no lifetime diagnosis of MDD or an anxiety disorder as assessed by the CIDI and reported low depressive symptoms at baseline (K-10 score < 16 and Inventory of Depressive Symptoms score < 4). The NESDA and NTR studies were approved by the Central Ethics Committee on Research Involving Human Subjects of the VU University Medical Center, Amsterdam, an Institutional Review Board certified by the US Office of Human Research Protections (IRB number IRB-2991 under Federal wide Assurance-3703; IRB/institute codes, NESDA 03-183; NTR 03-180). All subjects provided written informed consent.

Genetics of Recurrent Early-Onset Depression (4)

Subjects with recurrent ( $\geq 2$  episodes) or chronic ( $\geq 3$  years) MDD with onset <31 years old were recruited by six research groups: D. Levinson (Stanford University); M. Weissman (Columbia University); R. DePaulo (Johns Hopkins; PI now is James Potash); William Scheftner (Rush Presbyterian Medical Center, Chicago); R. Raymond Crowe (University of Iowa; PI now is William Coryell); George Zubenko (University of Pittsburgh, although this site no longer participates in the ongoing study, and its specimens were accessed through the NIMH repository after public release). There was a single protocol at all sites. All subjects gave signed, informed consent, on forms approved by the IRB at the PI's institution as above. Subjects were interviewed with the DIGS 3.0; family informant if available was interviewed with FIGS; and psychiatric records were obtained where possible. Diagnoses were assigned based on all information by consensus of two independent experienced research clinicians. Control subjects were from the Molecular Genetics of Schizophrenia GAIN project. We then selected a subset of controls who did not report recurrent major depression by CIDI-SF instrument criteria (which are known to identify over 30% false positives).

Glaxo-Smith-Kline (GSK) (5)

Cases diagnosed with recurrent MDD and age- and sex-matched unaffected controls were recruited at the Max-Planck Institute of Psychiatry in Munich, Germany and from two satellite hospitals in the Munich metropolitan area (BKH Augsburg and Klinikum Ingolstadt). All cases were evaluated using the semi-structured Schedules for Clinical Assessment in Neuropsychiatry (SCAN). The SCAN was administered by experienced research assistants who had completed training at World Health Organization Training and Research Centers. Each participant completed a questionnaire covering demography, family and individual history as well as medical history and ancestry. Cases were included in the study if they received a diagnosis of recurrent MDD ( $\geq 2$  separate episodes of MDD) of moderate or severe intensity

according to DSM-IV or ICD-10 . Cases were excluded from the study if they had experienced mood incongruent psychotic symptoms, a lifetime history of intravenous drug use or diagnosis of drug dependence, depression secondary to alcohol or substance abuse, or depression as clear consequence of medical illnesses or use of medications. Cases with diagnosis of schizophrenia, schizoaffective disorders, and other axis I disorders other than anxiety disorders were excluded from the study. Controls were selected randomly from a Munich-based community sample and recruited at the Max-Planck Institute of Psychiatry. They were screened for the presence of anxiety and mood disorders using the CIDI Screener. Only individuals without lifetime mood and anxiety disorders were included as controls. All subjects are independent from the MPIP collection below.

#### MDD2000 (6)

The original MDD2000 study was a case-only study with MDD cases recruited by three research groups: Queensland Institute for Medical Research (QIMR), VU University Amsterdam and VU Medical Centre. The MDD2000 samples were genotyped on the Affymetrix 6.0 platform (A6.0). These cases were combined with other cases and controls into the study published as the MDD2000+ association study (6). In the published study, the cases genotyped on the A6.0 were compared with the MGS controls (also used as controls for the GenRED and STAR\*D samples). Dividing the control set between three studies would lead to reduced power for each analysis. For this reason the MDD2000 A6.0 sample was excluded from the mega-analysis. However, genotype and phenotype data are available on the NIMH website to allow case-only analyses. Briefly, QIMR (N=941) cases were from the population-based Australian Twin Registry (see below). The VUMC cases (N=127) were drawn from the same studies as GAIN (see above). All cases were unrelated and independent from the GAIN MDD study. UEDIN cases (N=373) of recurrent MDD were recruited from inpatient and outpatient services of Royal Edinburgh Hospital and other psychiatric hospitals in southeastern Scotland. All subjects are of

North European ancestry. The diagnosis of MDD was per DSM-IV criteria (consensus between two psychiatrists) using data from direct interview by a psychiatrist (SADS-L) supplemented by clinical interviews and medical record review. Particular attention was paid to exclude cases with bipolar spectrum disorders. Patient consent allows de-identified samples to be sent abroad and used by academic and commercial collaborators and phenotype and genotype data can be used in meta-analyses.

The published MDD2000+ study also included additional cases and controls from QIMR referred to as the I317, I370 and I610 sets (named to reflect the genotyping platforms, Illumina 317K, 370K and 610K). Since publication of reference (6), some QIMR samples had been re-genotyped on the I610K platform. In addition, some QIMR cases from the A6.0 sample in (6) had been genotyped on an Illumina platform. Lastly, since publication of (6) additional screened QIMR controls had been genotyped. Briefly, MDD cases and controls were identified through psychiatric questionnaires administered to adult twins and their families recruited through the Australian Twin Registry (ATR, <http://www.twins.org.au>) under collaborative grant funding to QIMR and the Washington University in St. Louis. The structured interviews were either the shortened Composite International Diagnostic Interview (CIDI) (10) or the SSAGA-OZ interview (a modified version of the Semi-Structured Assessment for the Genetics of Alcoholism) (11), comprehensive psychiatric interviews designed to assess MDD and other psychiatric disorders according to DSM-IV criteria. The interviews were administered by trained telephone interviewers, closely supervised by a clinical psychologist. Only unrelated individuals were included. All participants provided written informed consent under study protocols approved by the QIMR Human Research Ethics Committee. Unrelated controls were selected as genotyped individuals from families in which no individuals qualified for diagnoses of MDD or anxiety disorders. If multiple controls were available from a family, the individual with the lowest neuroticism score was preferentially selected, otherwise an individual was selected at random. QIMR samples are analyzed as two sets MDD2000-QIMR\_317 (those genotyped on the

Illumina 317K or 370K platforms) and MDD2000-QIMR\_610 (those genotyped on the Illumina 610K platform).

#### Max Planck Institute of Psychiatry, Munich (12)

Cases were admitted to the hospital of the Max Planck Institute of Psychiatry (MPI-P), Munich, Germany, for treatment of MDD. Patients were included in the study within 1-3 days of admission, and the diagnosis was ascertained by trained psychiatrists according to DSM-IV criteria. Patients with MDD due to a medical or neurological condition were excluded. Ancestry was estimated using a self-report sheet for nationality, first language and ethnicity of the subject and of all grandparents. Controls were randomly drawn from Munich community registries and were screened with a modified version of the Munich-Composite-International-Diagnostic Interview (DIA-X/M-CIDI) for the absence of a lifetime history of axis I disorders. All included patients and controls were of Caucasian descent. The study was approved by the local ethics committee and written informed consent obtained from all subjects. All subjects are independent from the GSK collection above.

#### RADIANT (8)

Cases for the RADIANT MDD study arise from three multi-center cohorts (DeCC, DeNt, GENDEP) using the same clinical tools. Cases were ascertained from clinical centers in the UK and Europe, with one US center. All cases met DSM-IV criteria for MDD after review of all available information by senior study psychiatrists. Cases were interviewed (SCAN and other measures), and consensus diagnoses assigned by research clinicians. Controls were ascertained from UK and screened for absence of MDD using the Past History Schedule. Study protocols were reviewed and approved in advance by IRBs at participating institutions. All subjects provided written informed consent. Only UK cases were included in the published GWAS (8) following concerns regarding the difficulty of effectively controlling for genetic ancestry where cases and controls are sampled from different European centers with differing

ancestry (13). All RADIANT controls were from the UK, leading to a correlation between affected status and ancestry. In this study design, controlling for test statistic inflation using principal components corrects out the genetic differences between cases and controls due to both ancestry and affected status, reducing power of the study to detect association. We therefore analyzed only MDD cases ascertained in the UK, to match with the ascertainment of controls (RADIANT-UK). This strategy was confirmed by the use of profile scoring (14) . Briefly, we used association results from other data (“discovery”) sets from within the PGC-MDD to construct profile scores in the RADIANT data sets. A profile score for each individual is the sum of the logarithm of the odds ratios for each allele as estimated from the discovery data set, summed across all SNPs. We compared the variance explained in case control status in the RADIANT-UK vs the total RADIANT data set. We found that the variance explained in the RADIANT-UK set was consistently greater than in the total RADIANT data set and the non-UK cases were discarded. Ancestry principal components from the German cases of the RADIANT study showed that they grouped, as expected, with the other German samples in the PGC-MDD consortium. Since the RADIANT-GERMANY cases were genotyped on the same platform as the Bonn/Mannheim sample they were analyzed together with this data set.

#### Sequenced Treatment Alternatives to Relieve Depression (9)

MDD cases were recruited from participants in the STAR\*D trial; they consented separately to give DNA for genetic studies. The STAR\*D trial was a large NIMH-sponsored treatment trial involving 4,041 subjects that was designed to assess effectiveness of antidepressant treatments in generalizable samples, and to determine outcomes for outpatients with non-psychotic MDD treated with citalopram. To increase the generalizability of the findings, STAR\*D utilized broad inclusion criteria and enrolled an ethnically diverse population. Diagnosis was made using the Psychiatric Diagnostic Screening Questionnaire, and depressive symptoms were assessed with the 16-item Quick Inventory of Depressive Symptomatology. Patients with

bipolar, psychotic, or obsessive-compulsive disorders were excluded, as were those with primary eating disorders, general medical conditions that contraindicated study medications, substance dependence requiring inpatient detoxification, and clear non-response or intolerance to any protocol antidepressant during current episode or those who were pregnant or breast-feeding. Controls were MGS subjects, as described above for GenRED.

## REFINING THE DISCOVERY SAMPLES

### ***Relatedness***

Using 8,549 autosomal SNPs directly genotyped on all subjects and in approximate linkage equilibrium, we estimated the relatedness of all cases and controls using the “--genome” command in PLINK (15). Individuals with evidence of first- or second-degree relatedness were resolved by keeping one member of the relative pair (preference for cases).

### ***Restructuring***

Controls were known to be shared in GenRED and STAR\*D, and controls were proportionally distributed between these studies. In addition, the RADIANT sample had individuals from the UK and Germany; UK subjects were analyzed separately. MDS results (below) showed that the German subjects were similar to Bonn-Mannheim subjects and these were combined. The rationale for splitting the MDD2000 samples into two groups of QIMR samples only is described above.

**MDD REPLICATION PHASE: STUDIES & SAMPLES**

**Table S3** summarizes the seven samples used in the replication phase.

**Table S3: MDD replication studies**

See below for sample acronyms. US=United States. UK=United Kingdom. Clin=clinical ascertainment. Pop=population-based ascertainment. Vol=volunteer sample.						

### deCODE

Cases and controls were all Icelandic and were recruited from all over Iceland. For patients, diagnoses were assigned according to DSM-III or ICD-10 criteria. Controls were recruited as a part of various genetic programs at deCODE (excluding the schizophrenia, bipolar disorder, and anxiety projects) and were not screened for psychiatric disorders. Approval for the study was granted by the National Bioethics Committee of Iceland and the Icelandic Data Protection Authority. Informed consent was obtained for all participants.

### GenPod/NEWMEDS

A full description of the methodology and sample of the GenPod study can be found elsewhere (16). The study was a multi-centre randomized clinical trial of 601 patients with MDD recruited in primary care in three centers in the UK (Bristol, Birmingham and Newcastle).

Individuals were included who had an ICD-10 diagnosis of MDD of at least moderate severity as assessed by the Clinical Interview Schedule-Revised (CIS-R) (19) and a Beck Depression Inventory (20) score > 14. A subset of subjects of European ancestry were chosen for genotyping. Blood-derived DNA samples were genotyped on Illumina Human 660W-Quad bead chips at the University of Geneva Medical School (Geneva, Switzerland) as part of the NEWMEDS project (<http://www.newmeds-europe.com>). Individuals were aged between 18-74 years with a mean age of 38.8 years. Exclusion criteria were psychosis, bipolar disorder or major substance or alcohol abuse, and medical contraindications to antidepressants. All participants provided written informed consent. Ethical approval was obtained from the South West Ethics Committee (MREC 02/6/076) as well as research governance approval from Bristol, Manchester and Newcastle Primary Care NHS Trusts. Control individuals came from the Wellcome Trust Case Control Consortium (WTCCC) (21).

#### Harvard i2b2

Cases were identified using the Partners Healthcare electronic medical record (EMR). Using data available in the EMR, patients who met the following inclusion criteria were identified: a minimum of one ICD-9 code for MDD (ICD9 296.2x, 296.3x), at least one antidepressant prescription, and at least three outpatient psychiatry visit notes. Patients with both a past antidepressant prescription and at least two electroconvulsive therapy procedures (CPT: 90870, 90871) within one week were also included. Exclusion criteria included a past history of bipolar disorder (ICD-9: 296.1x, 296.4x-296.9x), dementia/delirium (ICD-9: 290.x), psychotic disorder (ICD-9: 295.x, 298.x), or past bone marrow transplant. De-identified, discarded blood specimens were obtained for subjects meeting these criteria who had presented for routine blood draw. Genotyping was restricted to individuals who identified as having European ancestry. The Partners Institutional Review Board approved all aspects of this study. Controls were identified from a healthy volunteer sample, age 18-35, participating in the

MGH Brain Genomics Superstruct Project and were screened to have no history of psychiatric or neurologic illness or treatment with psychoactive drugs.

### PsyCoLaus

Subjects were selected from subjects of European ancestry from a community survey (CoLaus) carried out in the city of Lausanne, Switzerland (17). Subjects were randomly selected from a complete list of the Lausanne inhabitants aged 35-75 years. All 35 to 66-year old participants were invited by letters also to participate in the psychiatric evaluation (PsyCoLaus) (22). Sixty-seven percent of the participants of the CoLaus study in the age range between 35-66 years accepted the psychiatric evaluation, which resulted in a sample of 3,719 individuals, of whom 92% were of European ancestry. Psychiatric assessment in the PsyCoLaus sub-study included the semi structured Diagnostic Interview for Genetic Studies (DIGS), French version (23). Cases met DSM-IV criteria for MDD and controls were devoid of any psychiatric disorders. A subset of the 3,419 European subjects who received full psychiatric assessment and gave consent for genetic testing were selected for GWAS genotyping. This research was approved by the local institutional review board. All participants received a detailed description of the goal and funding of the study and signed a written informed consent.

### SHIP-LEGEND

Data from the Study of Health in Pomerania (SHIP) were used (24, 25). The target population was comprised of adult German residents in northeastern Germany living in 3 cities and 29 communities, with a total population of 212,157. A two-stage stratified cluster sample of adults aged 20-79 years (baseline) was randomly drawn from local population registries. The net sample (without migrated or deceased persons) comprised 6,267 eligible subjects of whom 4,308 Caucasian subjects participated at baseline SHIP-0 between 1997 and 2001. Follow-up examination (SHIP-1) was conducted 5 years after baseline and included 3,300 subjects. In 2007, the “Life-Events and Gene-Environment Interaction in Depression” (LEGEND) study was

started based on SHIP (18). The lifetime diagnosis of MDD was assessed with the Munich-Composite International Diagnostic Interview (M-CIDI). The M-CIDI is a standardized fully structured instrument for assessing psychiatric disorders over the life span according to DSM-IV criteria. The computerized version of the interview was used by clinically experienced interviewers (psychologists) in a face-to-face situation. All interviewers had undergone intensive and continuous training in the diagnostic procedures. SHIP and LEGEND were approved by the local Institutional Review Board and conformed to the principles of the Declaration of Helsinki.

### TwinGene

The TwinGene project, conducted between 2004 and 2008, is a population-based Swedish study of twins born between 1911 and 1958 drawn from the Swedish Twin Registry (26). All subjects in this investigation were independent (i.e., one twin selected per twin pair). The study participants previously participated in a telephone interview called Screening Across the Lifespan Twin Study (SALT). Data from the SALT study were used to identify MDD cases as either reporting antidepressant use or meeting DSM-IV criteria for MDD using the Composite International Diagnostic Interview Short Form (CIDI-SF) criteria. The study was approved by the local ethics committee at Karolinska Institutet and all participants gave informed consent.

### Genetics of Recurrent Early-Onset Depression Phase II

The second phase of GenRED was included as a replication sample (the first phase was a discovery sample) (4). GenRED2 included new cases meeting the same criteria as in GenRED (see above), plus new controls. Dr. Janet Sobell (University of Southern California) contributed 287 post-QC controls from the Mayo DNA Bank which consists of long-term, community medicine patients (Mayo Clinic, Rochester, MN) who were undergoing venipuncture for any reason. Consenting individuals ages 45 and above completed a brief demographic and psychiatric screening questionnaire. Extensive medical records were screened for evidence of psychiatric illness. Individuals were excluded if they were judged likely to have had a mood or

psychotic disorder on the basis of a review of medical records, taking into account the recorded diagnoses and treatment in each case (including major disorders as well as possible proxies for a mood disorder in older nomenclature such as adjustment disorders, depression NOS, anxiety state, etc.). The final subset was selected to roughly match the proportions of self-reported ancestry in the GenRED 1+2 sample. Drs. Carlos Pato and James Knowles contributed 187 post-QC controls from the Genomic Psychiatry Consortium, an ongoing study of schizophrenia and bipolar disorder. Controls were recruited opportunistically in the Los Angeles area and screened with a self-report questionnaire. We selected individuals who reported European ancestry in all grandparents and answered negatively to five screening questions for lifetime bipolar disorder, five for lifetime schizophrenia, and four for lifetime MDD. Note that these 1,305 subjects were genotyped at the same lab (Centrillion Biosciences, Mountain View, CA) and with the same GWAS array (Illumina Omni1-Quad) as the Depression Genes and Networks sample (below) collected by a subset of the GenRED investigators, so that these samples were combined for the PGC replication analysis.

#### Depression Genes and Networks

This sample was genotyped and analyzed in combination with the GenRED2 sample (above). A survey research company (Knowledge Networks, Menlo Park, CA) recruited the 471 post-QC recurrent MDD cases and 470 never-depressed controls from participants in an online survey panel that is recruited on an ongoing basis using random digit dialing of nationally-representative US households. (Note that the same panel was used to recruit the Molecular Genetics of Schizophrenia control sample for the NIMH repository, but individuals who were invited to be screened for MGS and who were still members of the panel were not invited to be screened for DGN.) Online screening was carried out using the CIDI-SF depression and alcohol and substance dependence modules; prospective controls were selected who reported two or more episodes meeting criteria for MDD but denied lifetime substance dependence, while

prospective controls denied ever having two or more weeks of depressed mood or anhedonia and two or more other MDD criteria outside of acute bereavement. These individuals were then interviewed (SCID) and individuals not meeting the initial eligibility criteria (based on final review by the site PI) were excluded. Note that these cases all reported recurrent MDD, but were not required to meet the additional criteria required for the GenRED project.

#### **MDD-BIPOLAR DISORDER (BIP) CROSS-DISORDER ANALYSIS**

The PGC BIP mega-analysis (27) included 7,481 cases with BIP and 9,250 controls in its discovery phase. The BIP samples went through the same QC pipeline used for the MDD data (described above). The main issue in comparing these samples is overlapping controls. The same control samples were used for many of the MDD and BIP samples (i.e., the NIMH/MGS controls and the WTCCC1 controls), and some groups had MDD and BIP case groups and a common set of controls. We used identity-by-state comparisons to identify samples that were included in multiple PGC MDD and BIP samples. Any overlapping controls were randomly allocated to yield comparisons of independent cases and independent controls both within and between the MDD and BIP samples. Thus, the sample sizes for this particular analysis are different from the MDD discovery phase and from those in the PGC BIP paper (27).

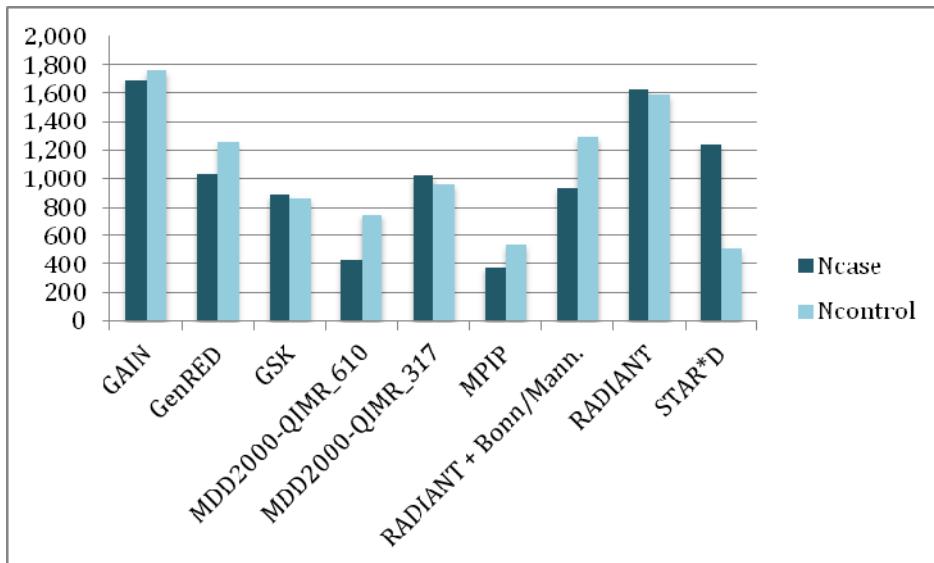

### SAMPLE SIZES FOR DISCOVERY & REPLICATION PHASES

The discovery and replication sample sizes are given in **Table S4**. The totals are below.

Discovery phase: 18,759 subjects (9,240 MDD cases and 9,519 controls). **Figure S5** depicts a bar chart of the discovery phase numbers of cases and controls. MDD replication phase: 57,478 subjects (6,783 MDD cases and 50,695 controls). MDD-BIP cross-disorder analysis: after resolving overlapping samples, there were 32,050 independent subjects (9,238 MDD cases plus 8,039 controls and 6,998 BIP cases plus 7,775 controls).

**Table S4: Sample sizes for the discovery mega-analysis and replication phases**

Phase	Sample	SNPs	Total subjects	Cases	Controls

**Figure S5: Bar chart of discovery phase sample sizes*****SNP selection for replication*****MDD replication**

The discovery SNP results were grouped into regions defined by linkage disequilibrium using an iterative process after ranking all SNPs by association p-value: if a SNP has  $r^2 > 0.2$  (based on analysis of HapMap3 CEU+TSI using Haploview) to a more significantly associated SNP located  $\pm 1\text{Mb}$ , the SNP is assigned to the region defined by the more strongly associated SNP. Distinct regions (i.e., associated variants within  $\pm 200\text{kb}$ ) were tested for independence using conditional analysis. For the MDD replication samples, the top SNP in each region was tested for association, and standard error-weighted meta-analysis was used for the replication samples alone, and for the combination of PGC discovery and replication data.

**MDD-BIP cross-disorder analysis**

We selected SNPs for analysis of that had  $p < 0.0001$  in the MDD samples (160 SNPs) or in the BIP samples (659 SNPs) from a total of 1,241,611 autosomal directly genotyped and

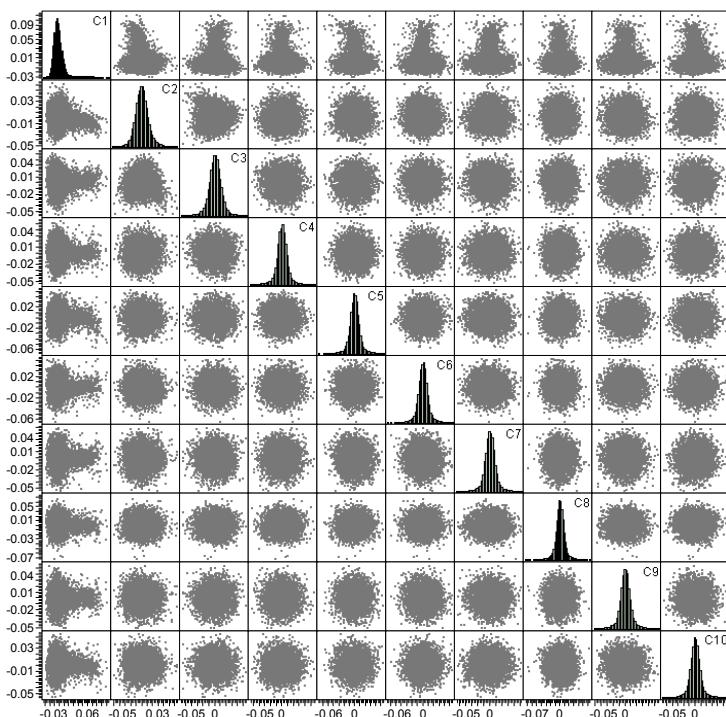

imputed SNPs. These SNP lists differ from the primary samples due to the need to eliminate sample overlap. As no SNP was on both lists, there were 819 total SNPs.

### ASSESSMENT OF ANCESTRY

Population stratification can bias association results. Methods to handle this risk have been developed and are now standard in the field. We identified 8,549 autosomal SNPs directly genotyped on all subjects and in approximate linkage equilibrium, and used multidimensional scaling (MDS) in PLINK (15) to extract 10 MDS scores per subject. MDS is essentially identical to principal components analysis (28).

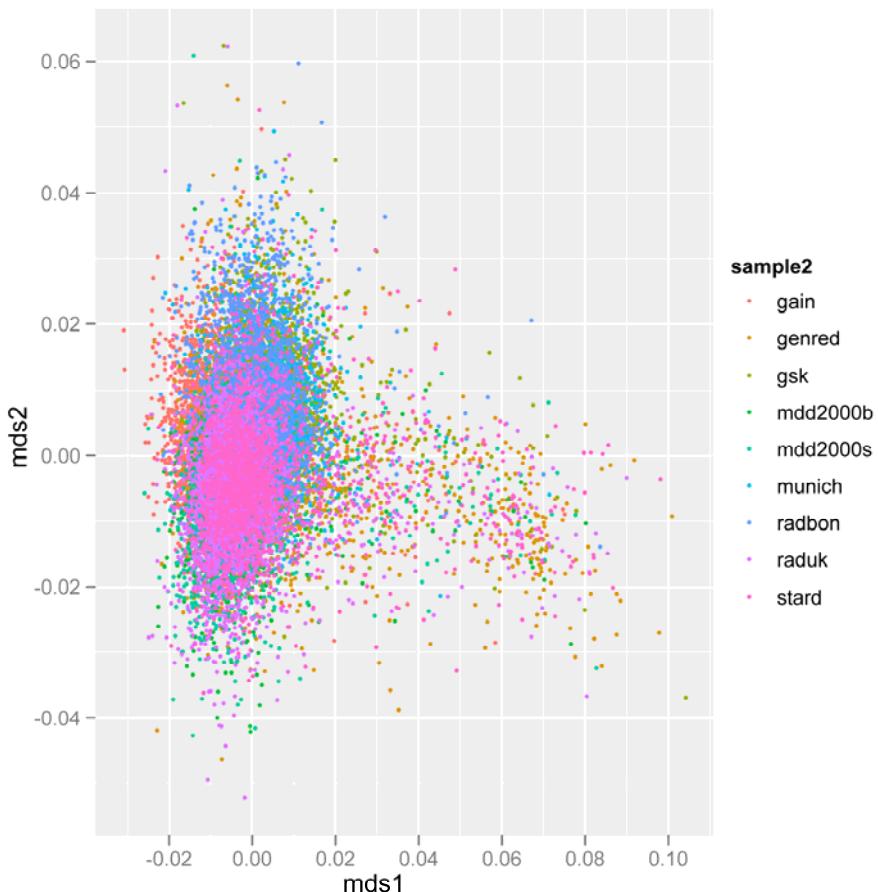

We present the MDS results in multiple ways. **Figure S6** shows the interrelation of the 10 MDS values for all subjects. MDS1 and MDS2 are the most variable. The clusters for MDS3-10 are globular suggesting that these dimensions capture little variability.

**Figure S6: Interrelation of 10 MDS dimensions on all discovery samples**

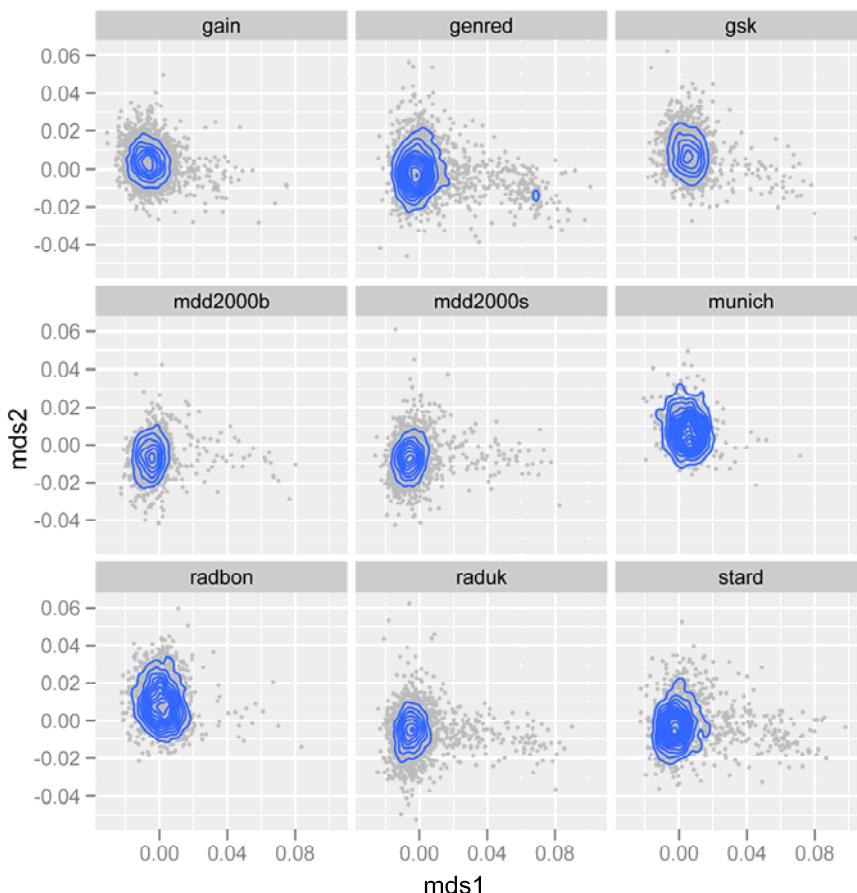

**Figure S7** plots MDS2 x MDS1 for the whole discovery sample (this is essentially an enlargement of the graph in row 2, column 1 of Figure S6). Most subjects fall within a central cluster. There is modest diversity along MDS 1 and MDS2. In the legend, mdd2000b is the MDD2000\_QIMR\_610 sample and mdd2000ks is the MDD2000\_QIMR\_317 sample.

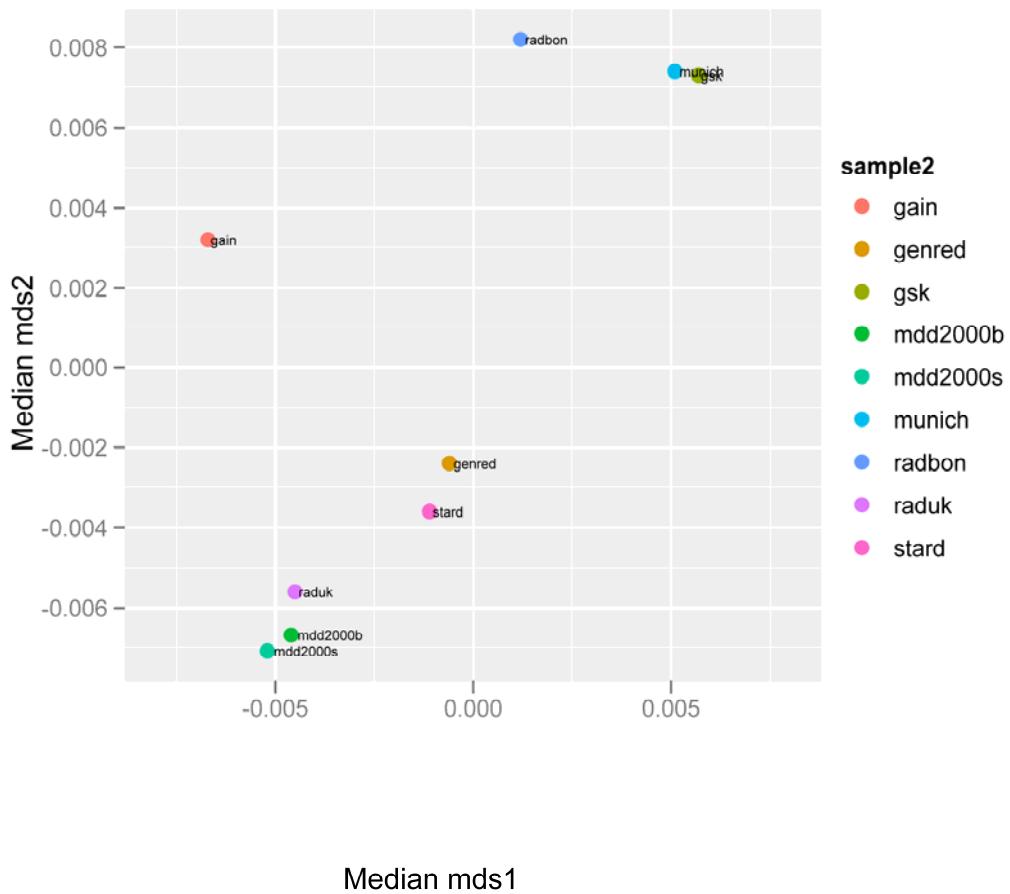

**Figure S7: MDS plots for the discovery sample**

**Figure S8** stratifies Figure S7 by study in order to evaluate differences by study (not visible in Figure S7 as the central cluster contains >17,000 points). The blue circles in Figure S8 show the density of points. All studies have a globular central cluster with minor degrees of outliers along MDS1. The locations of the clusters are similar between studies. The mdd2000b is the MDD2000\_QIMR\_610 sample and mdd2000ks is the MDD2000\_QIMR\_317 sample.

**Figure S8: MDS plots by sample**

**Figure S9** shows the median values for MDS1 and MDS2 per study to enable clearer comparisons of the discovery samples. Overall, the variation between studies is not large and the relative locations of the sample medians are consistent with the sample origins. The studies fall into four geographical subgroups. (a) The three samples from Germany are in the upper right (with the two southern German samples overlapping). (b) The GAIN sample from the Netherlands is on the left. (c) The two US samples (GenRED and STAR\*D) cluster together. (d) The UK RADIANT sample and the two Australian samples cluster together in the lower left. In the legend, mdd2000b is the MDD2000\_QIMR\_610 sample and mdd2000ks is the MDD2000\_QIMR\_317 sample.

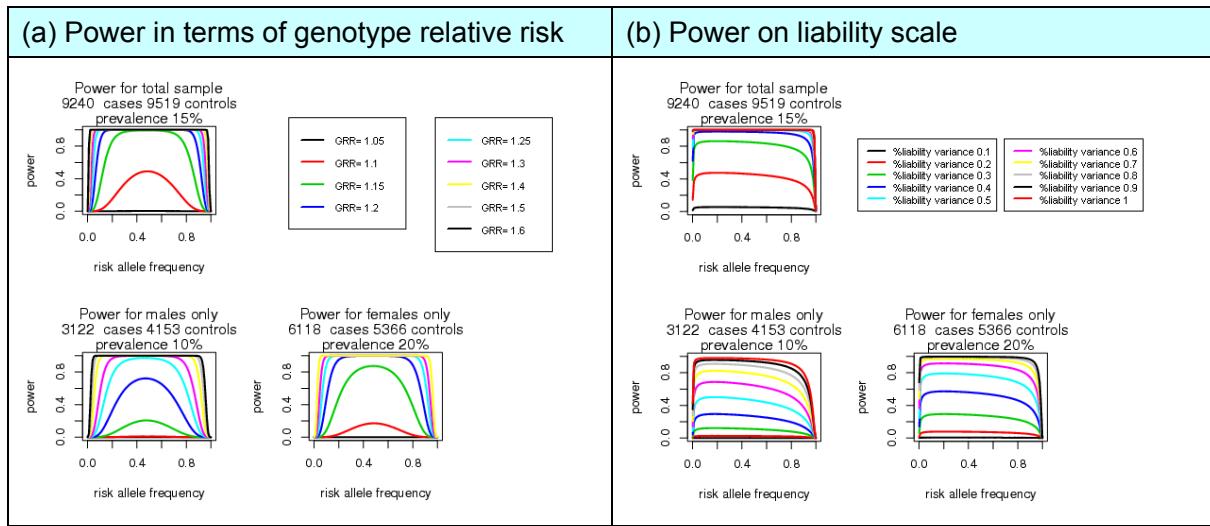

**Figure S9: MDS plot showing sample medians**

### STATISTICAL POWER

We present power calculation curves (**Figure S10**) in two ways (both assuming type I probability level of  $5 \times 10^{-8}$ ), firstly expressed in the terms of the genotype relative risk (GRR) of the heterozygote. Although this is the usual way to express power it can be somewhat misleading for diseases of high prevalence. For example, we have 86% power to detect a variant with GRR of 1.15 (assuming prevalence of 15%, risk allele frequency 0.2, significance level  $5 \times 10^{-8}$ ) compared to 55% power to detect a variant of GRR of 1.15 in a case-control study of the same size for a disorder of prevalence 1%. This is counter-intuitive because on the liability scale the cases of the less prevalent disease must be more extreme than cases of the

more common disease. In fact, for this example, the locus explains 0.3% of the variance in liability for a disorder with prevalence of 15% compared to only 0.1% of the variance in liability for a disorder of prevalence of 1%. Therefore we also express power in terms of the variance in liability of a risk allele.

**Figure S10: Statistical power of the discovery sample**

## SECONDARY ANALYSES

We undertook a number of pre-defined secondary analyses intended to evaluate genetic heterogeneity between MDD cases.

### Sex

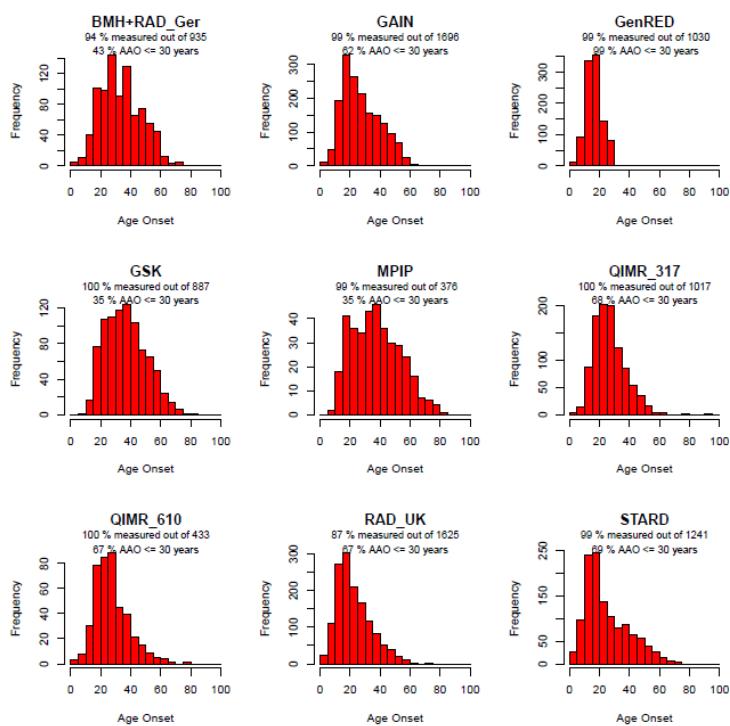

As the lifetime prevalence of MDD is approximately two times greater in females (29, 30), we conducted GWAS separately in males and females to evaluate sex-specific genetic risk variants.

### **Recurrent and recurrent-early onset MDD**

As recurrence and age of onset may index heterogeneity in MDD (31, 32), we conducted four sets of secondary analyses. The distributions of age of onset of first major depressive episode are shown in **Figure S11**. The GenRED study required onset  $\leq 30$  years.

First, we restricted MDD cases to those with early-onset ( $\leq 30$  years) and recurrence ( $\geq 2$  episodes) of MDD. Second, as pre-pubertal onset may be distinctive (33), we restricted MDD cases to those with childhood onset ( $\leq 12$  years). Third, to identify SNPs which are differentially associated with either early-onset or late-onset MDD, we analyzed association age of as a quantitative trait (a square root transformation was used to normalize the data and reported ages of onset  $< 5$  years were set to 5).

**Figure S11: Age of onset distributions for each sample**

***Latent class analysis***

The diagnosis of DSM-IV MDD requires endorsement of five of nine “A” criteria (depressed mood, loss of interest, appetite/weight gain or loss, hypersomnia/insomnia, psychomotor agitation/retardation, fatigue, feelings of worthlessness or guilt, diminished ability to think or concentrate or indecisiveness, and suicidal ideation). The A criteria were available for 88% of cases. Endorsement rates were somewhat variable between studies (**Table S12**), which reflects differences such as setting (e.g. clinical vs. community), ascertainment (e.g., MDD vs recurrent MDD), and assessment frame (e.g., a focus on lifetime worst vs current episode).

**Table S12. MDD A criteria endorsement rates by study**

Study	%not missing	MDD1	MDD2	MDD3a	MDD3b	MDD4a	MDD4b	MDD5a	MDD5b	MDD6	MDD7	MDD8	MDD9

STAR*D	100	92	95	33	25	89	10	25	23	93	86	87	37

**MDD A criteria**

- (1) depressed mood most of the day, nearly every day
- (2) markedly diminished interest or pleasure in all, or almost all, activities most of the day, nearly every day
- (3a) significant weight loss or decrease in appetite
- (3b) significant weight gain or increase in appetite
- (4a) insomnia nearly every day
- (4b) hypersomnia nearly every day
- (5a) psychomotor agitation nearly every day
- (5b) psychomotor retardation nearly every day
- (6) fatigue or loss of energy nearly every day
- (7) feelings of worthlessness or excessive or inappropriate guilt
- (8) diminished ability to think or concentrate, or indecisiveness
- (9) recurrent thoughts of death or suicide or a suicide attempt or a specific plan for committing suicide

We used LCA to evaluate item-level heterogeneity in MDD symptoms. Input data were binary MDD symptom data. Items 1 and 2 were excluded because endorsement of one of these items is required for a diagnosis of MDD resulting in very high endorsement rates in all studies. Items 3 (weight/appetite), 4 (sleep), and 5 (motor) were disaggregated to code increases and decreases separately.

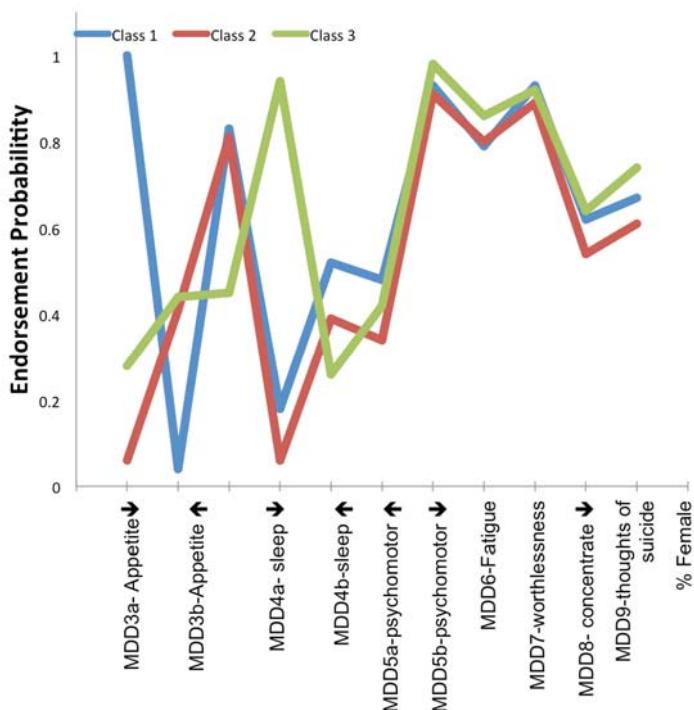

Latent class cluster models were fit to 10 binary item responses for MDD cases (items 3a, 3b, 4a, 4b, 5a, 5b, 6, 7, 8, and 9) using Latent GOLD (Statistical Innovations, v4.5). For each Latent GOLD run, up to 10,000 iterations of the EM algorithm were allowed using a convergence criterion of  $10^{-10}$ . Each LCA solution was restarted 100 times with new starting values to find the maximum likelihood estimates of the parameters. Individuals with missing item responses were included. After preliminary analyses, the final analysis was applied to all analysis samples fitting sex as a covariate. The fit of the latent class and latent factor models with differing number of classes/factors was compared using the Bayes Information Criterion (BIC), where  $BIC = -2LL_j + F_j * N$ , where  $LL_j$  is the maximum log likelihood achieved for a model fitting  $j$  latent classes,  $F_j$  is the number of free (estimated) parameters in the model  $F_j = 11*j - 1$ , where 11 reflects the 10 binary MDD items plus the sex covariate and  $N$  is the sample size ( $N=7,040$ ). The BIC takes account of the goodness of fit and the number of criteria needed to achieve that fit. The BIC is expected to lead to the correct choice of model for large samples.

Based on BIC, the most parsimonious model was a 2-factor 3-class model. Investigation of this model showed that the 3-classes represented severity levels with differences in the profile symptoms captured in the quantitative factor scores. The factor scores may be suitable for a case-only analysis, but our aim was an association analysis of controls vs multiple categories of cases. Allowing only latent classes, the six-class model, was most parsimonious based on BIC. However, some class sizes were small and profiles were not highly interpretable. We found that the three class solution provided interpretable differences and reasonably sized

classes. Additional analyses by sex and by site confirmed qualitatively the robustness of the 3 class solution.

Details of the three class solution are given in **Figure S13** and **Tables S14** and **S15**. The class frequencies were: 47%, 35%, and 18%. The numbers in the third class may be prohibitively small and assignments vary between sites for the reasons discussed above. Consistent with other studies (34, 35), these results provided empirical support for latent classes related to typical/atypical MDD subtypes. We used multinomial logistic regression (36) (including study indicators and five principle components as before) as the most powerful way to optimize the potential gain of power from sub-phenotyping versus loss of power from smaller case sample groups. The test of heterogeneity of allelic odds ratios between the classes identifies SNPs with differential association.

**Figure S13: Symptom endorsement per latent class**

Important discrimination comes from items 3a (weight loss), 3b (weight gain), 4a (insomnia), and 4b (hypersomnia). Note that MPIP does not have data on 3b and 4b, the latter will be hard to predict and so MPIP has few cases in the third cluster. RAD\_BDI is analysed together with BonnMH so the small class size will not be a problem.

**Table S14. Endorsement probabilities for each of the 3 clusters**

### POLYGENIC / RISK PROFILE ANALYSIS

Following our prior work (14), we reallocated the MDD discovery samples into discovery (~80%) and target sets (~20%) for polygenic / risk profile analysis. The polygenic discovery set consisted of 4,984 cases and 6,641 controls (the GSK, MPIP, STAR\*D, GAIN, QIMR\_317, QIMR\_610, and GenRED samples). The polygenic target set consisted for 2,524 cases and 2,824 controls (RADIANT-Bonn-Mannheim and RADIANT-UK).

We first conducted association analyses in the discovery set using a subset of 114,158 autosomal SNPs that had been subject to particularly strict QC and filtered so that the remaining

SNPs were in approximate linkage equilibrium. These SNPs were used to make a profile list (SNP rs ID, reference allele, and a the logistic regression beta coefficient as weight). This profile list was then applied to the independent target set to compute a summed weighted risk allele score for each case and each control. The risk profile scores of target cases and controls were then tested using analysis of variance. We considered the ability of SNPs beneath 10 p-value thresholds (pT) to predict case-control status in the target samples. The results are given in

**Table S22.****Table S22: Risk profile analyses.**

pT	SNPs with $p < pT$	Target sample p-value	$R^2$
0.0001	42	0.29	0.00027
0.001	343	0.011	0.00158
0.01	2,902	0.022	0.00126
0.05	11,835	4.6e-4	0.00297
0.1	21,365	3.0e-5	0.00422
0.2	38,048	5.4e-6	0.00502
0.3	52,948	5.0e-6	0.00506
0.4	66,108	9.2e-7	0.00585
0.5	77,695	6.8e-7	0.00599
1.0	114,158	7.9e-7	0.00592

SNPs identified in the polygenic discovery sample have a highly significant relationship with case-control status in the target samples for pT of 0.05 and greater. Although highly significant, the proportion of variance explained is small ( $R^2 \sim 0.6\%, 0.04\%$  expected by chance).

SNP positions according to NCBI Build 36/UCSC hg18. OR=odds ratio. SE=standard error. a1 is the reference allele. Ngt=number of samples in which SNP directly genotyped (versus imputed).

**TABLE S17. TOP REGIONS IN MDD DISCOVERY PHASE**

The SNP in the “SNP” column is the index SNP along with its position, p-value, odds ratio, standard error, and direction of effect in the discovery samples. SNPs in region shows the SNPs in the region and their  $r^2$  (in parentheses) with the index SNP. The genes column lists genes  $\pm$  300 kb of the index SNP.

**TABLE S18. MDD DISCOVERY, MDD REPLICATION, AND COMBINED RESULTS**
