

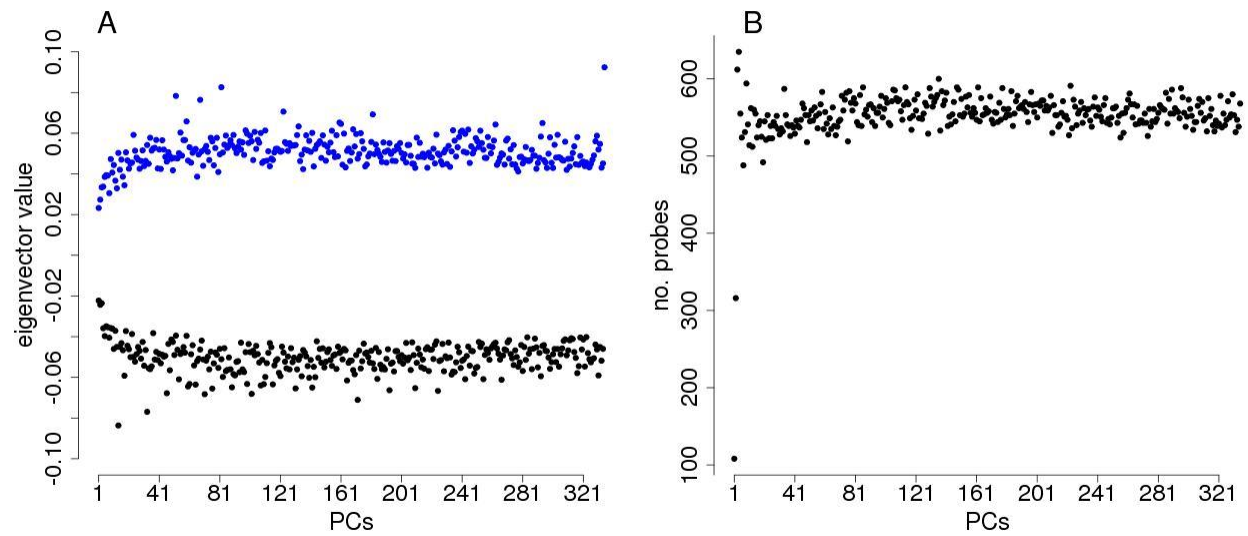

**Figure S1** Scores plots of PCs against their adjacent vectors. Demonstrates a homogenous population with no clear substructure or independent clustering of groups of individuals.

**Figure S2** Selection of probes driving PCs. (S2A) Maximum (blue) and minimum (black) eigenvector values for each PC. The eigenvector values represent the extent of the correlation between a probe and a PC, with 0 indicating no association. Selection of probes driving each PC is based on the optimal number of probes for each PC that have the same eigenvector value cut off. As multiple probes can contribute a small amount of variance to each PC it is reasonable that a low cut off value can pick up many of the significant probes driving each PC. Probes that have an eigenvector value of greater than 0.02 or less than -0.02 were selected for further biological enrichment analysis as this incorporated all the maximally and minimally expressed probes in this section. (S2B) Selection of probes at this cut off value enabled approximately similar numbers of probes to be selected for each PC. The slightly lower number of probes that are selected in the initial PCs is due to the lower maximum and minimum eigenvector values in these PCs as shown in (S2A).

**Figure S3** Variance explained by PCs. Calculated from the eigenvalues obtained from the Singular Value Decomposition. Variance explained by each PC is plotted in black and cumulative variance in blue. A) Normalized dataset, B) Corrected with linear models, C) PC25 corrected D) PC50 corrected. All variances add up to 1. Cum

**Figure S4** Correlation between additive genetic and common environmental factors. Significant association ( $p = 8.57 \times 10^{-8}$  and  $R^2=0.08$ ) between the common environment and genetic components estimated in an AC and AE models. The proportion of common environment variance was calculated by dividing the variance attributed to common environment ( $V_c$ ) by the total phenotypic variance ( $V_p$ ). The proportion of genetic variability (heritability) was calculated by dividing the additive genetic component ( $V_g$ ) by the total phenotypic variance ( $V_p$ ). This result indicates that the heritability estimates obtained are confounded with common environment variance and therefore inflated upwards by common family effects.

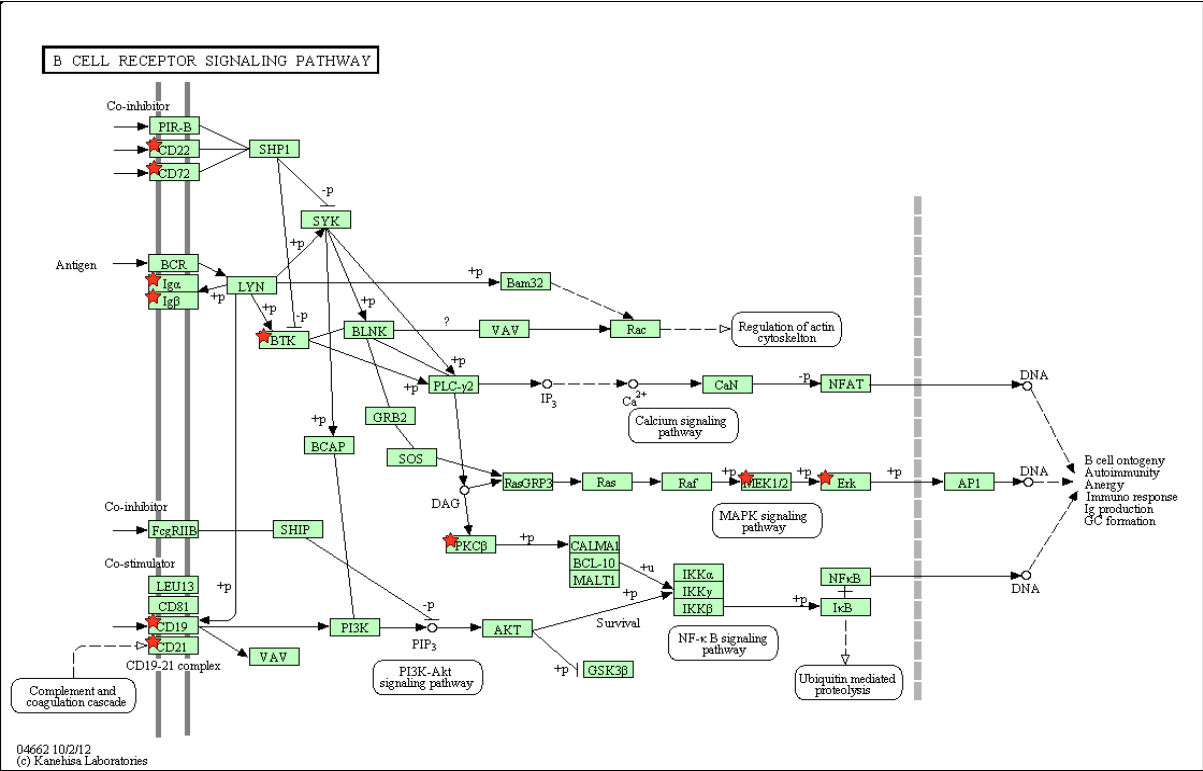

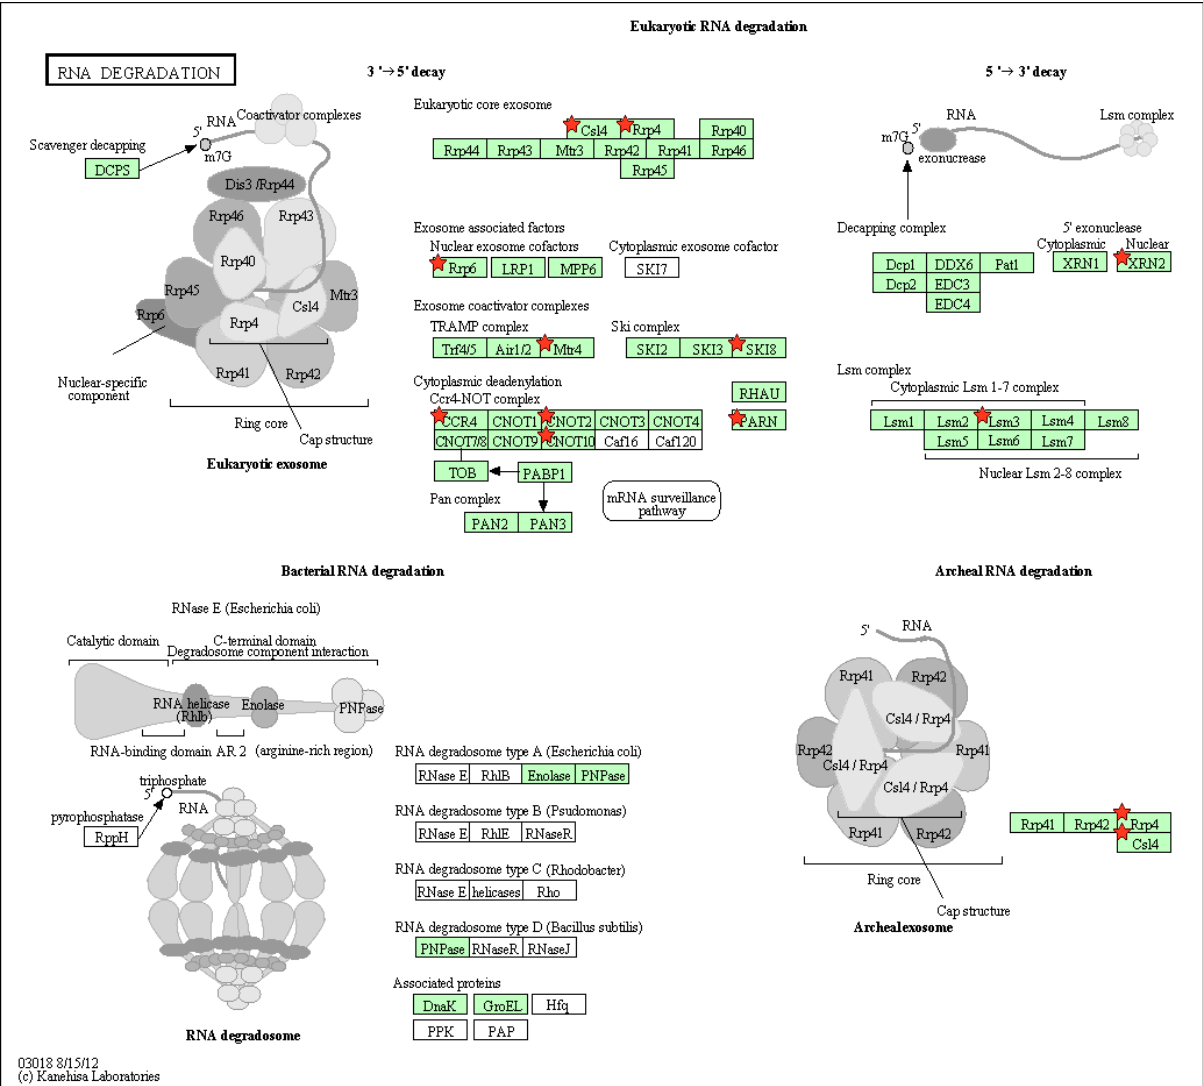

**Figure S5** Manhattan and QQ plots. Manhattan and QQ plots for each PC with a significant SNP associated in Table S1. The significance value cut-off is drawn as a red line drawn on the Manhattan plots and is based on the Bonferroni correction for each PC. The QQ plot shows the expected p-values vs. the observed p-values in the study and the lambda value gives a numerical estimation of any inflation in the statistics.

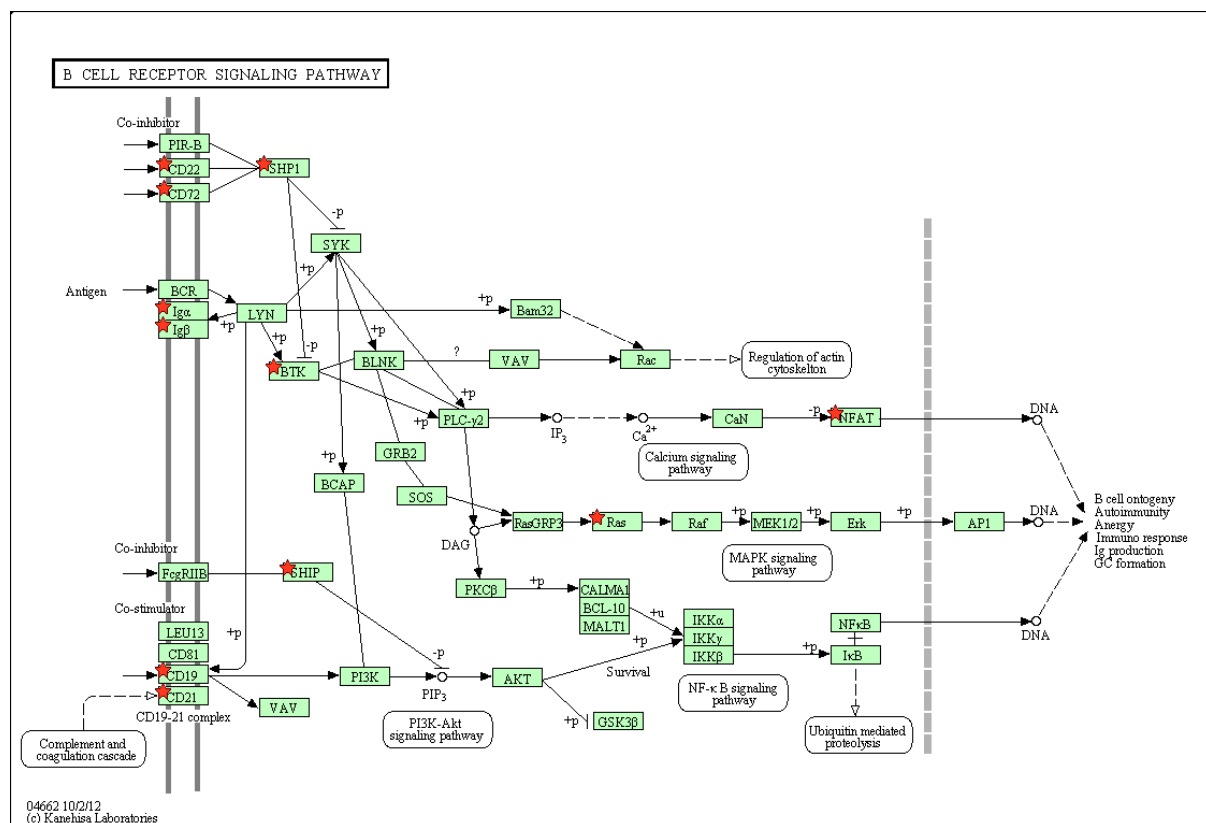

**Figure S6** Pathway diagrams of enriched biological networks. Figures generated from the KEGG pathway database. Pathway analysis for PC1-50 was performed using DAVID Bioinformatics Resources 6.7, Functional Annotation Tool. These pathways were significant after multiple correction (FDR) (Table S2). Components highlighted with red stars represent probes present within the corresponding PC. PC1 shows enrichment for ribosomal components. PC3 is enriched for Fc gamma R-mediated phagocytosis. PC7 is enriched for porphyrin metabolism. PC8 shows enrichment for enzymatic subunits involved oxidative phosphorylation, PC12 is enriched in components involved in the B-cell receptor signaling pathway and hematopoietic cell lineage. PC13 is enriched for RNA degradation. PC18 shows enrichment for ribosomal components and PC25 shows enrichment for B-cell reception signaling.

**Table S1 Results from the GWAS for each PC.** Probes that were found to be significant after a Bonferroni correction (0.05/488,462 SNPs) on each PC are listed in this table. Though none of these are significant after correcting for all PCs, they are significant at an empirical p-value of 0.05 for each PC after 1000 permutations. PC – principal component, CHR – chromosome, SNP – SNP ID, BP – base pair, BETA – regression coefficient, STAT – Coefficient T-statistic, P – Asymptotic p-value for t-statistic, EMP – empirical p-value after 1000 permutations.
